Wave modes depend on the complete model

Field count is not, by itself, a mode count or interface-system dimension.

Classical elastic / thermoelastic

Mechanical displacement; temperature enters only when the coupled thermoelastic equations are included.

Relaxation, phase-lag, thermal-displacement, memory, or fractional models

Thermal branches and their speeds/support depend on the selected operator, parameters, and initial-boundary da

Piezoelectric and other coupled-field media

Electrical, porous, magnetic, or carrier fields alter the eigenproblem; quasi-electrostatic models are not EM-wave r

Micropolar, gradient, and nonlocal media

Additional kinematics or spatial operators change boundary data and dispersion in model-specific ways.

No universal mode count, speed, attenuation, or interface-matrix size is asserted.

Derive and classify roots from the actual field equations and boundary conditions.
