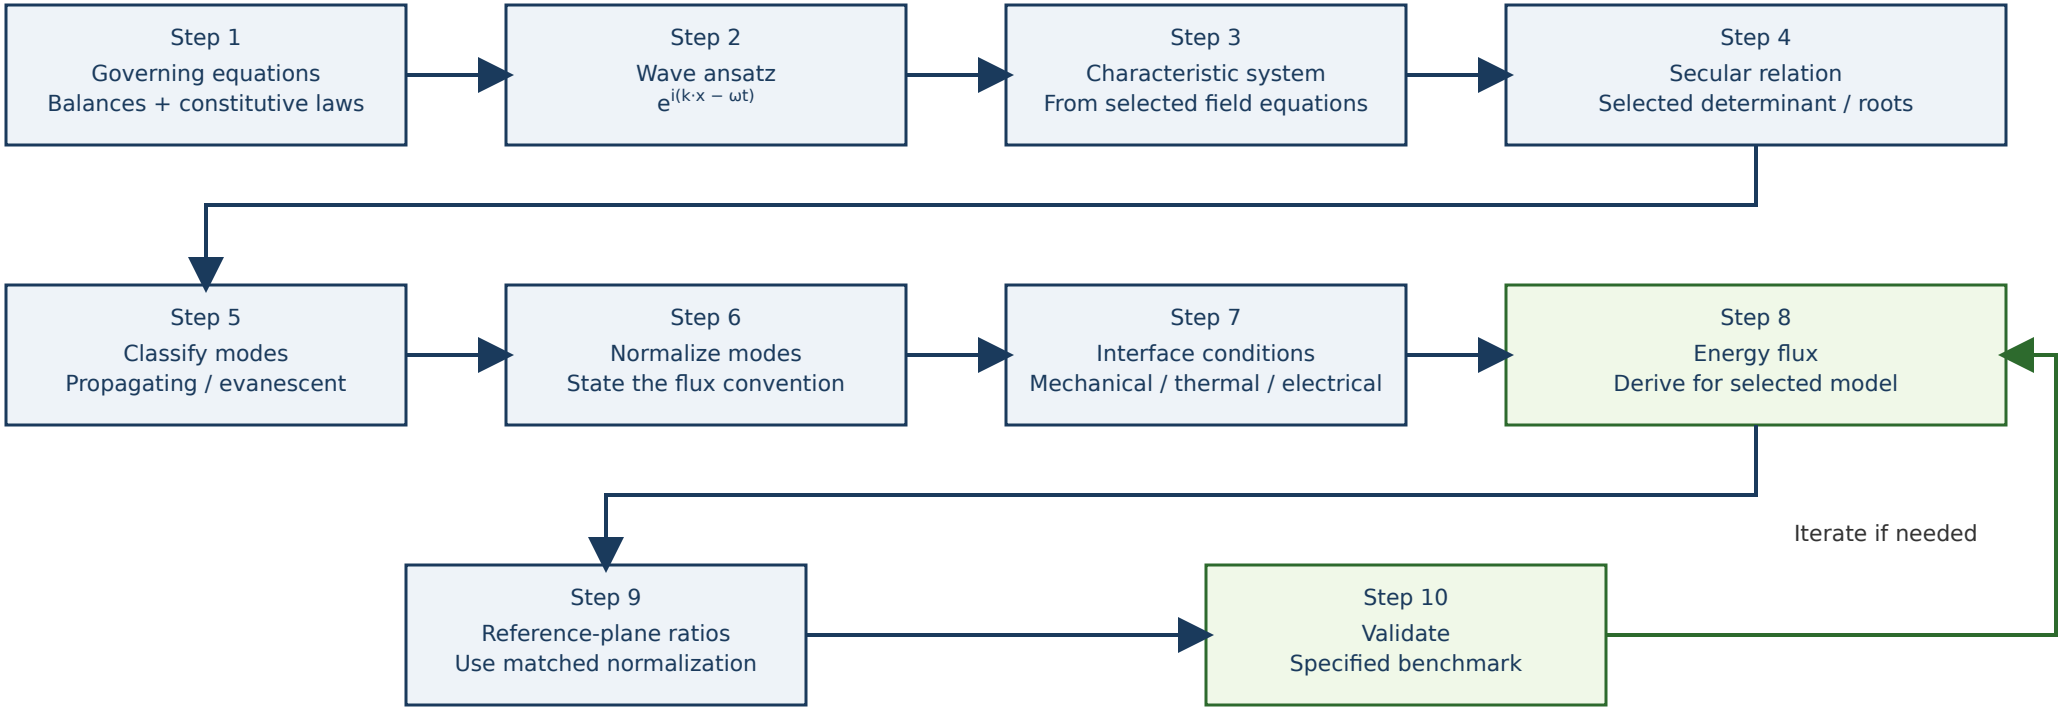
Model-specific workflow for wave propagation

From selected field equations to energy-flux comparison (Sections 8, 9, 10)



Method notes

Steps 1–4: Select the model, geometry, data, and characteristic system.

Steps 5–6: Classify and normalize modes under a stated convention.

Step 7: Apply the selected mechanical, thermal, and (if present) electrical conditions.

Step 8: Derive the complete model-specific flux; do not assume a universal formula.

Steps 9–10: Match reference planes; validate only against specified benchmark evidence.

Complex/evanescent modes require careful normalization; no universal ratio closure is implied.
